

# GSOC Raspberry Pi - PHOTOBOTH project

Last updated June 3, 2020

## Congratulations on setting up the Raspberry Pi !!!

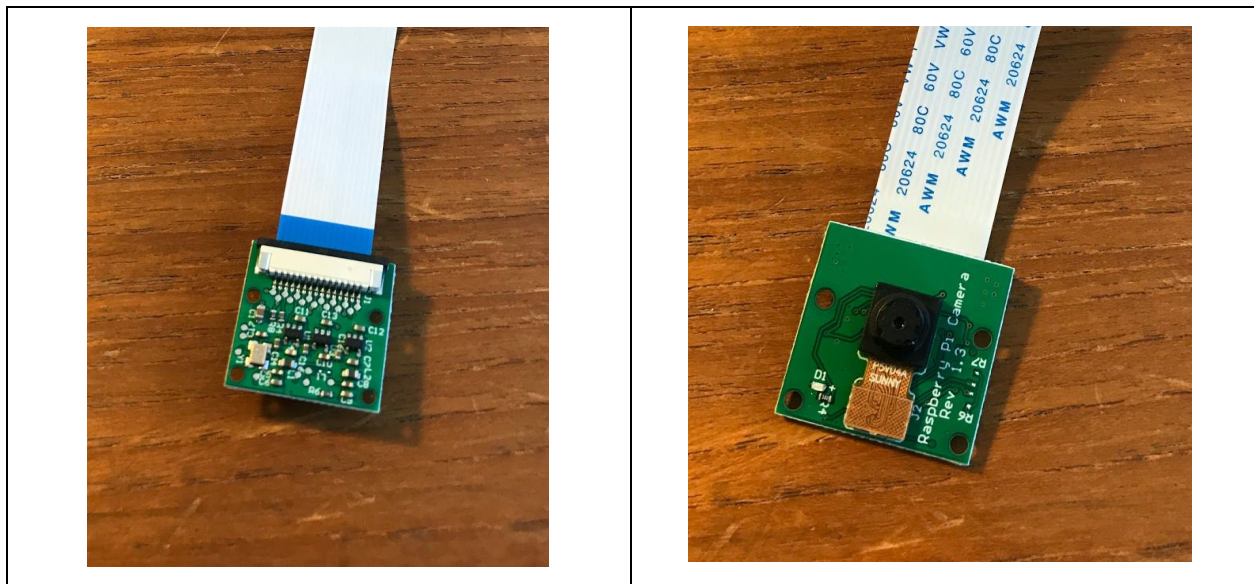

Let's work on a fun project! We'll learn how to add a camera to the Raspberry Pi, and test the camera, and then write a Python photobooth program to control the camera, along with a Python slideshow program to display our photobooth pictures.

After setting up your Raspberry Pi, go ahead and pull the small white box labeled CAMERA from within the GSOC Raspberry Pi Box. That's the only "hardware" we will need for this project. You'll also need some tape (scotch or blue tape) or alternatively a little bit of playdough to attach the camera board to the monitor.

## **STEP #1 Attach the camera to the Raspberry PI**

**IMPORTANT! You need to power down (i.e. be sure the micro USB power cable is OUT of the Raspberry Pi) before attaching the camera!**

Each end of the camera ribbon cable is "blue" on one side and has a shiny silver connector on the other side. The left photo shows the blue side connected to the "circuit side" of the camera module. The right photo shows the other side of the camera module, which is the lens of the camera.

There are two black connector ports on the Raspberry Pi board, one on the side opposite of the USB ports (labeled DISPLAY) and the other next to the HDMI port (labeled CAMERA). Gently pull up the edges of the CAMERA port's black plastic clip, and slide the camera ribbon cable into the port as shown below so that the shiny side faces the Raspberry Pi's HDMI port.

Press down gently on the black plastic clip to lock the camera ribbon cable in place. Lightly tug up on the ribbon cable to be sure it is secure. You should be able to see a tiny bit of the silver connectors sticking out above the black connector port as shown below.

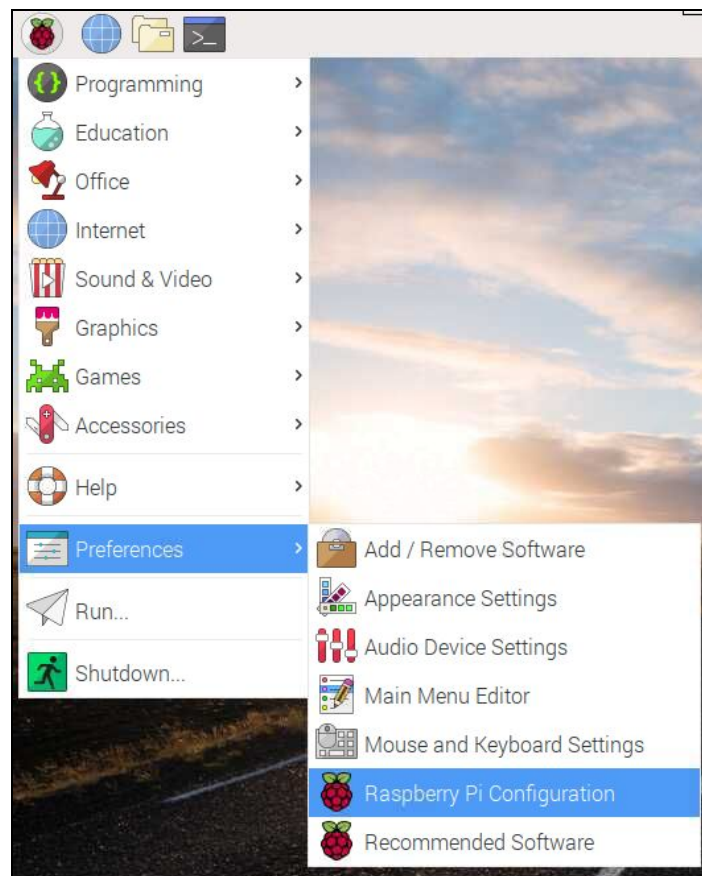

## **STEP #2 Carefully position the Raspberry Pi camera and micro USB cable**

Grab your tape (or playdough) and attach the camera board to the monitor (or something else) so the black camera lens is facing the direction you wish to take photos. You can now go ahead and attach the micro USB power cable to your Raspberry Pi as well at this point and power up the Raspberry Pi.

You should notice a small red LED on the camera board flash momentarily as the Raspberry Pi powers up. This confirms that the camera board is connected to the Raspberry Pi and receiving power.

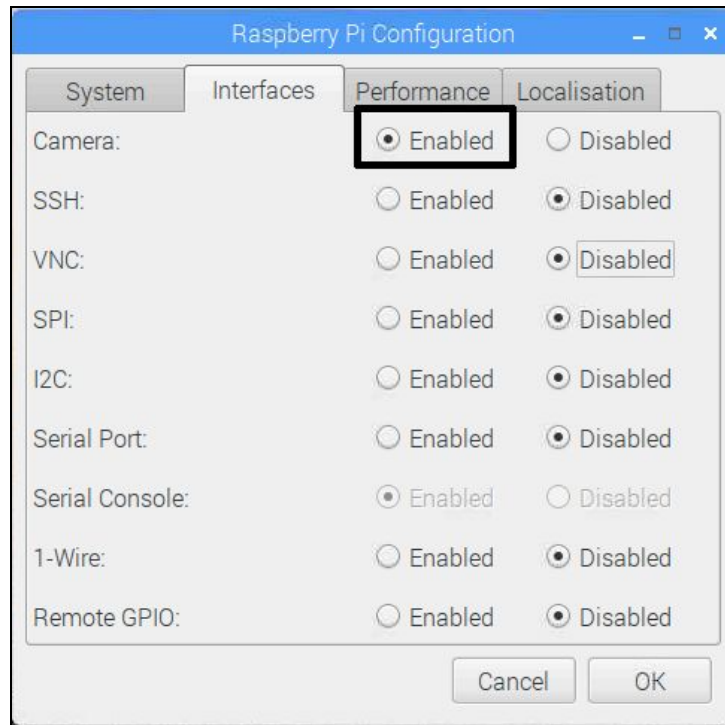

## **STEP #3 configure the Raspberry Pi for the camera (and then reboot)**

You'll need to verify that this Raspberry Pi has been configured to use the camera. Click on the Raspberry in the upper left corner of the screen to open the system menu, then select the menu items Preferences and Raspberry Pi Configuration menu items as shown below.

Next, click on the INTERFACES tab at the top of the Raspberry Pi Configuration dialog, and be sure the Camera interface radio button is set to Enabled as shown below.

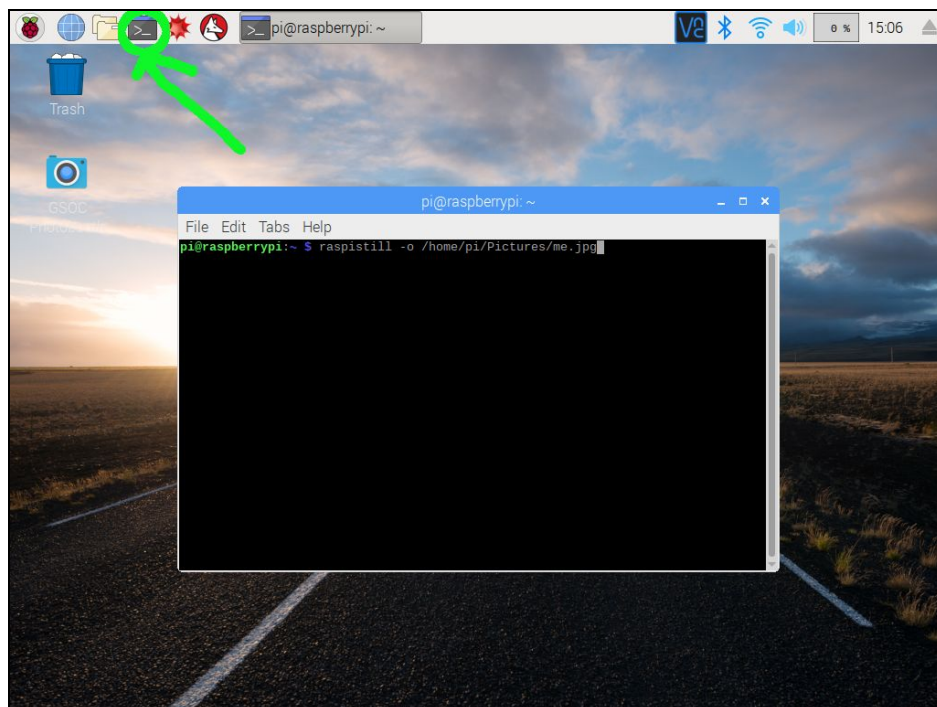

You will need to select OK to exit this dialog. If you had to change the Camera interface to Enabled, you will additionally need to REBOOT the Raspberry Pi before continuing. Select SHUTDOWN from the system menu and then REBOOT.

#### **STEP #4 use the raspistill program to take your picture!**

Click on the terminal icon (little black window) on top left of your Raspberry Pi screen to open a terminal window.

Type the following command at the terminal prompt:

```
raspistill -o /home/pi/Pictures/me.jpg
```

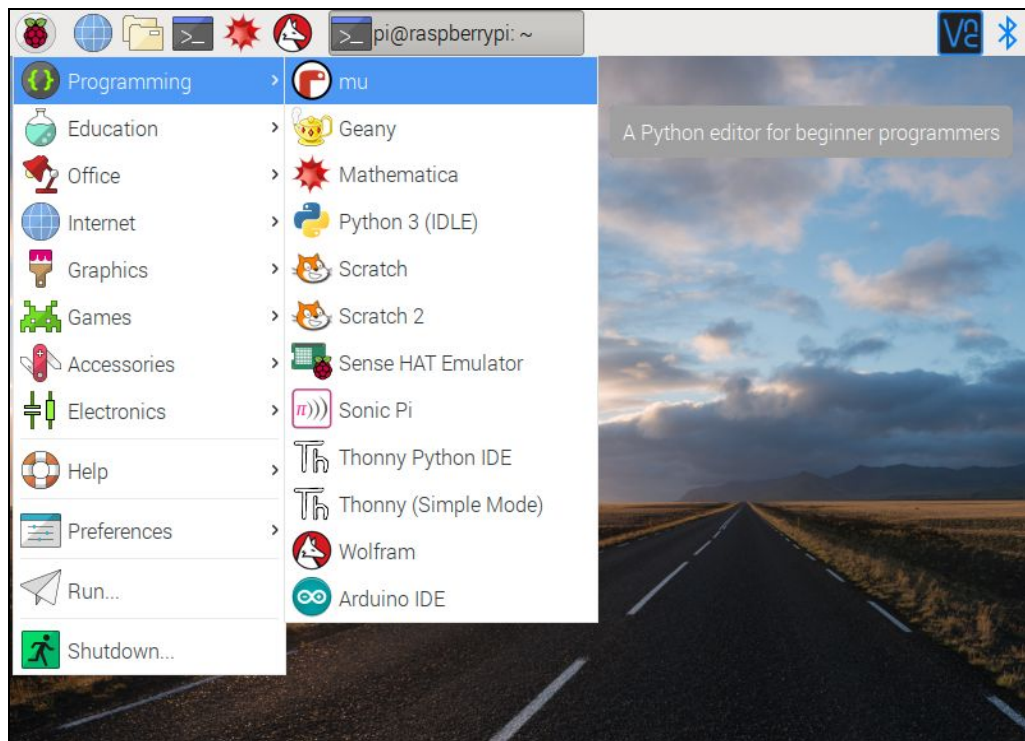

... and then press the enter key to execute the command. The red LED on the camera board will light up for a few seconds, after which a picture will be taken! The picture is saved to the file ME.JPG within the Raspberry Pi's /home/pi/Pictures folder. Use the folders tool on the Raspberry Pi's toolbar (to the left of the terminal tool) to navigate to the /home/pi/Pictures folder and click on the file ME.JPG to see your picture!

You can take pictures one at a time this way, but it's way more fun (and more interesting) to make your own PHOTOBOTH program.

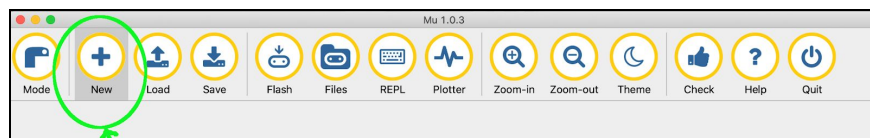

# BUILD YOUR OWN PHOTOBOOTH with PYTHON

## STEP #1 open up the MU python programming environment

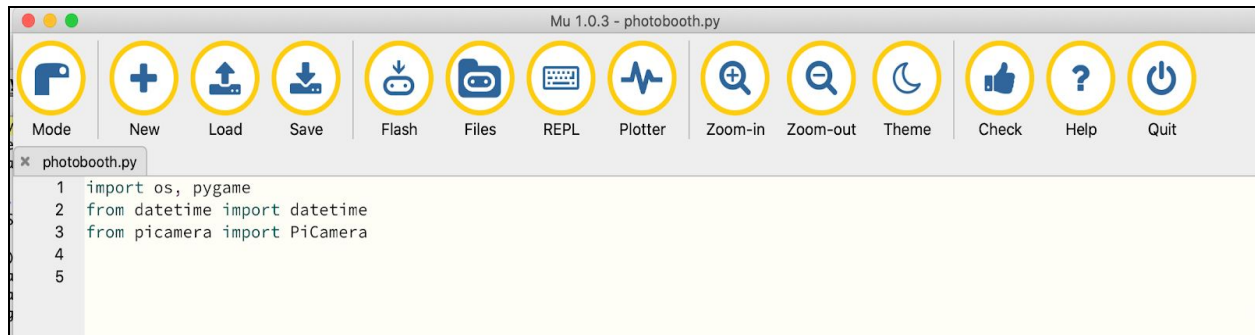

Click on the Raspberry in the upper left corner of the screen to display the system menu. Pick Programming and then “mu” menu items as shown in the image below.

Click on the mu editor's NEW button as shown:

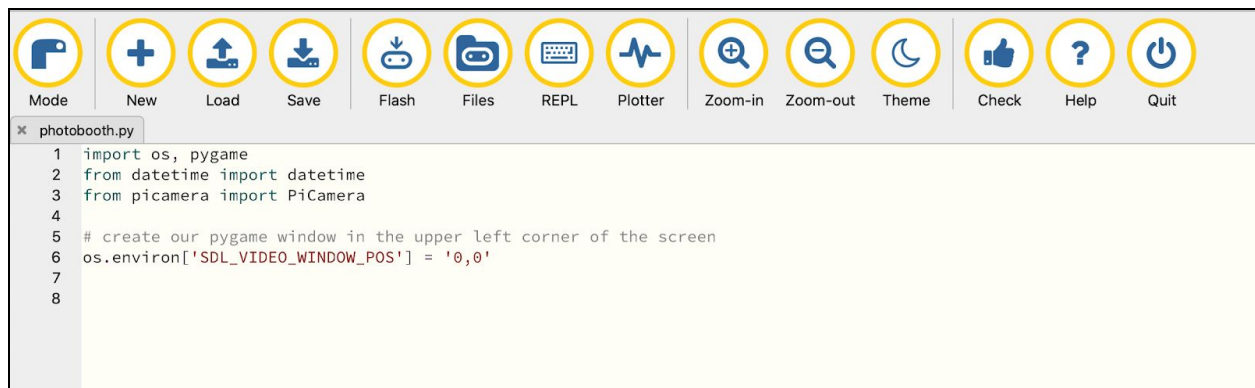

Click on the mu editor's SAVE button and save your program file as “photoboothFL” **where F is the first character of your first name and L is the first character of your last name.** The name photoboothFL.py will appear in the editor window's tab as shown in the following picture.

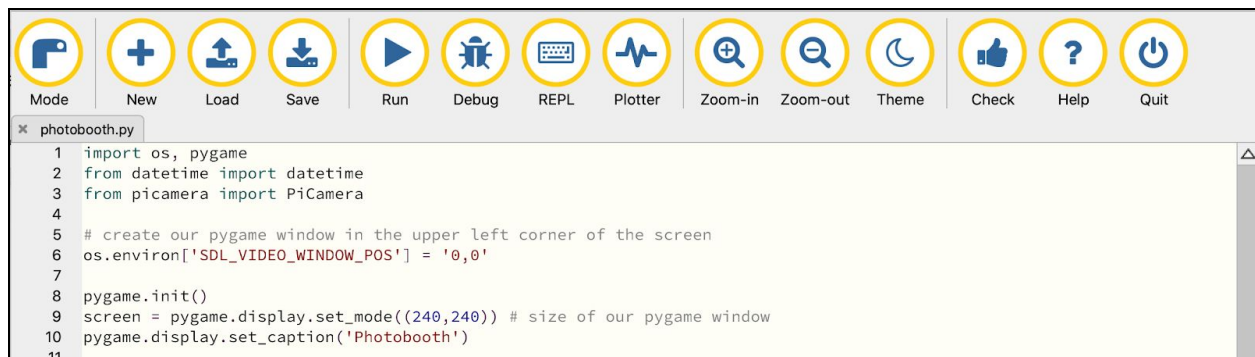

Python allows you to leverage the work of others (or yourself) by including modules, or other pieces of code, within your program. Almost every python program starts out this way!

Carefully copy the three lines shown above into your program.

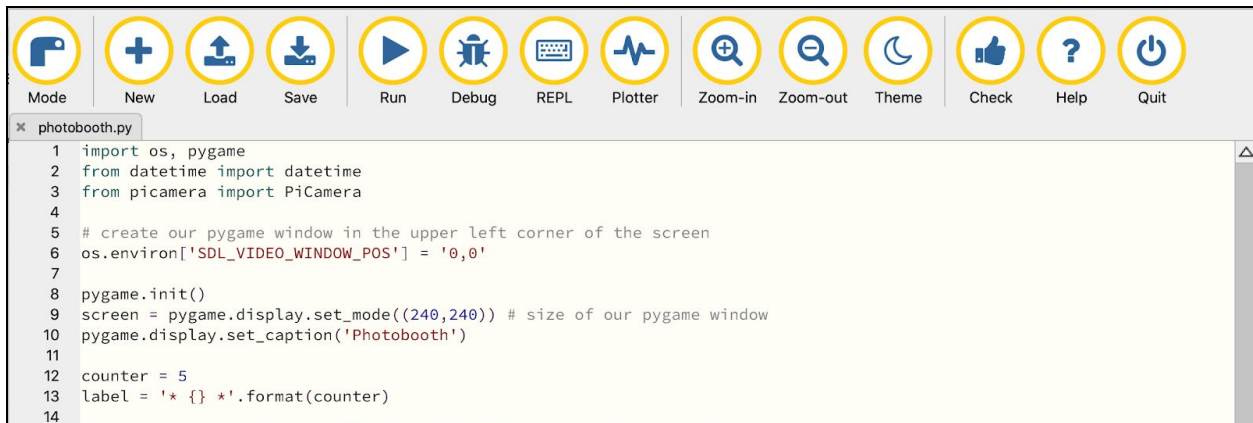

Here we import the “os” (operating system) module, the pygame module which we’ll use to create a countdown window, the datetime module which we’ll use to create the filenames for the pictures we take, and finally the picamera module, which contains the methods (i.e. “code”) we need to control our Raspberry Pi camera.

Within python, any text following the # symbol is a non-executable COMMENT. Here we’ve left a comment to ourselves to remind us that the line starting with “os.environ” is used to specify where our pygame window is drawn on our screen; in this case, the upper left most corner of our screen (position 0,0 is the upper left corner of the screen).

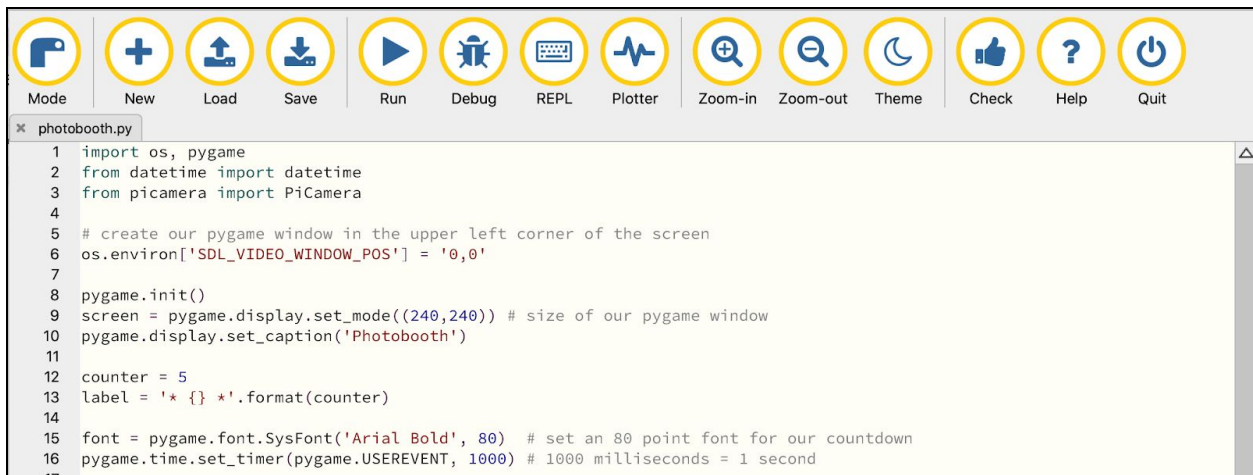

On line 8 we initialize the pygame system. We then set the size of our pygame window (240 x 240 pixels) and we add a title to our pygame window’s title bar.

```
1 import os, pygame
2 from datetime import datetime
3 from picamera import PiCamera
4
5 # create our pygame window in the upper left corner of the screen
6 os.environ['SDL_VIDEO_WINDOW_POS'] = '0,0'
7
8 pygame.init()
9 screen = pygame.display.set_mode((240,240)) # size of our pygame window
10 pygame.display.set_caption('Photobooth')
11
12 counter = 5
13 label = '* {} *'.format(counter)
14
```

Now we create two new variables for our own use. *Counter* holds our count down value (5, 4, 3, 2, 1 ...). *Label* is a string representation of our *counter* numerical variable that we “dress up” by adding asterisks alongside our numerical *counter* variable’s value. Within line 13 the { } symbols represent a variable that is set to the value of counter and displayed between two asterisks.

Hey don’t forget to click the SAVE button every time you add a few new lines of code!

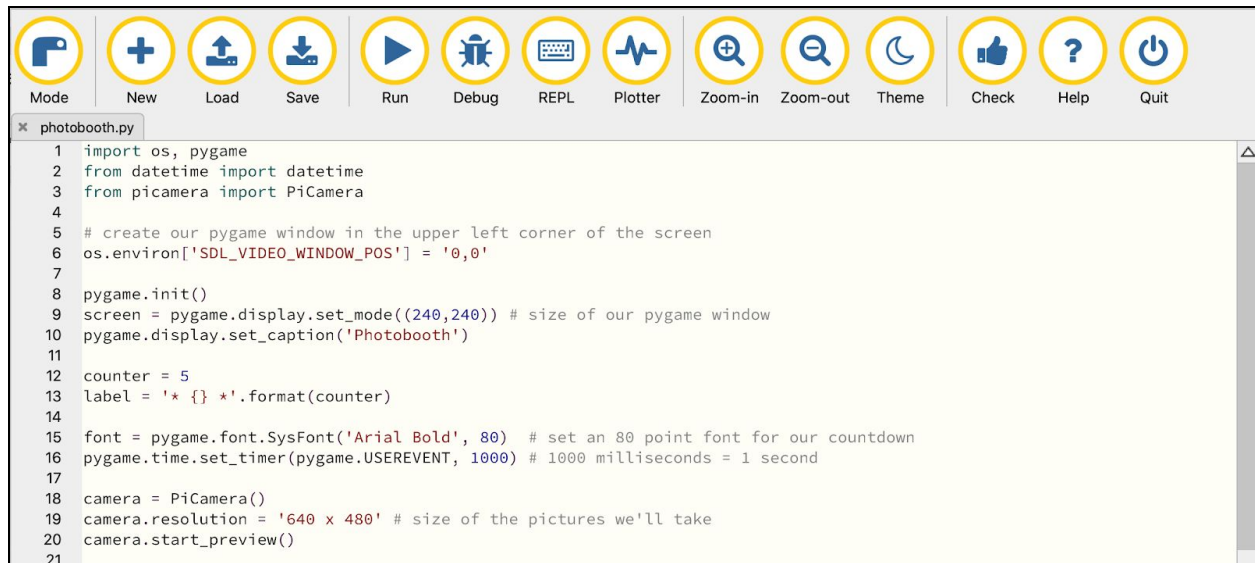

```
15 font = pygame.font.SysFont('Arial Bold', 80) # set an 80 point font for our countdown
16 pygame.time.set_timer(pygame.USEREVENT, 1000) # 1000 milliseconds = 1 second
17
```

On line 15 we set the font we’ll use within our pygame window. On line 16 we create an EVENT that fires off every second.

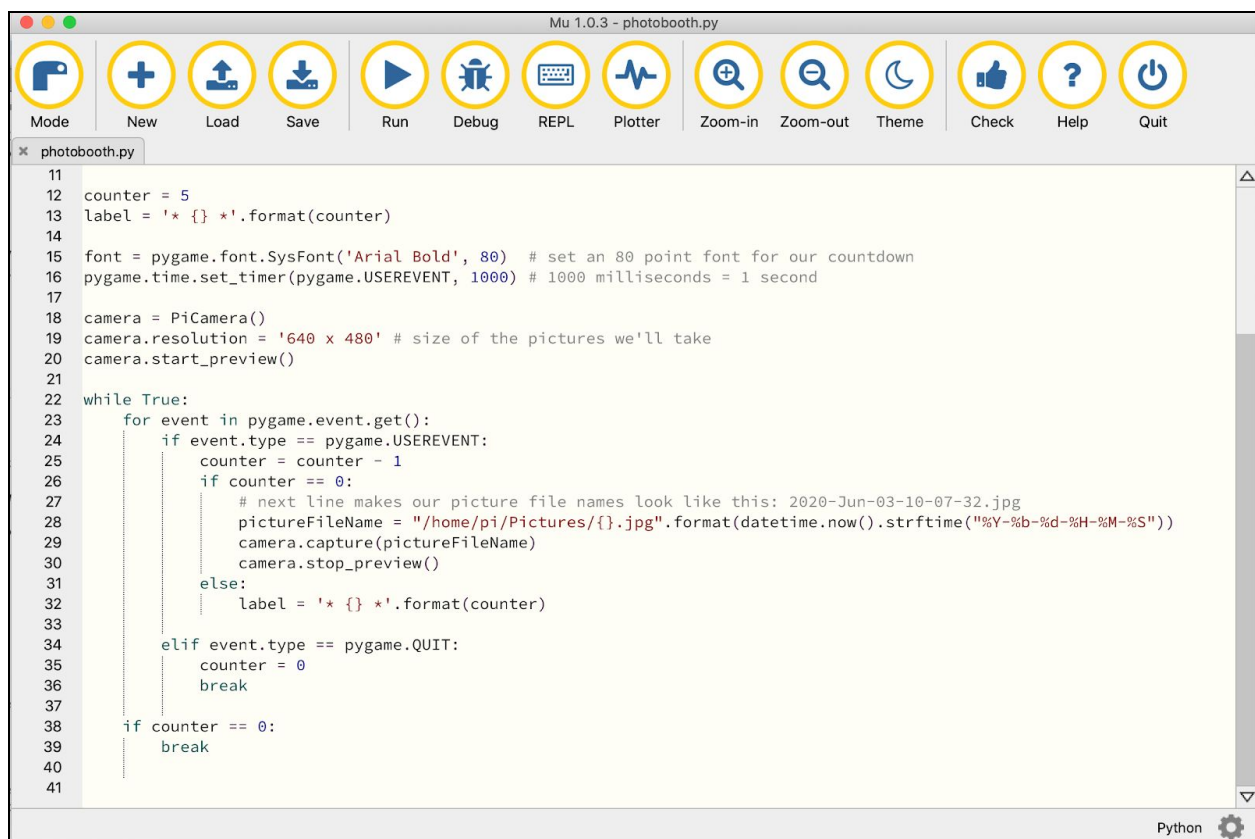

Windowed programs (e.g. Microsoft Windows, the Mac operating system, etc.) use what is called EVENT-based programming; an event loop runs continuously and your program “reacts” to events like the movement of the mouse, mouse clicks, menu selections, and so forth. On line 16 we created our own event that “fires” every second, which we can then “listen” for inside our pygame window’s event loop.

```
1 import os, pygame
2 from datetime import datetime
3 from picamera import PiCamera
4
5 # create our pygame window in the upper left corner of the screen
6 os.environ['SDL_VIDEO_WINDOW_POS'] = '0,0'
7
8 pygame.init()
9 screen = pygame.display.set_mode((240,240)) # size of our pygame window
10 pygame.display.set_caption('Photobooth')
11
12 counter = 5
13 label = '* {} *'.format(counter)
14
15 font = pygame.font.SysFont('Arial Bold', 80) # set an 80 point font for our countdown
16 pygame.time.set_timer(pygame.USEREVENT, 1000) # 1000 milliseconds = 1 second
17
18 camera = PiCamera()
19 camera.resolution = '640 x 480' # size of the pictures we'll take
20 camera.start_preview()
21
```

Line 18 creates a camera object variable; we'll use this object to control the Raspberry Pi camera. On line 19 we set the resolution of the pictures we will take, and then on line 20 we start up the camera by putting it into “preview mode”.

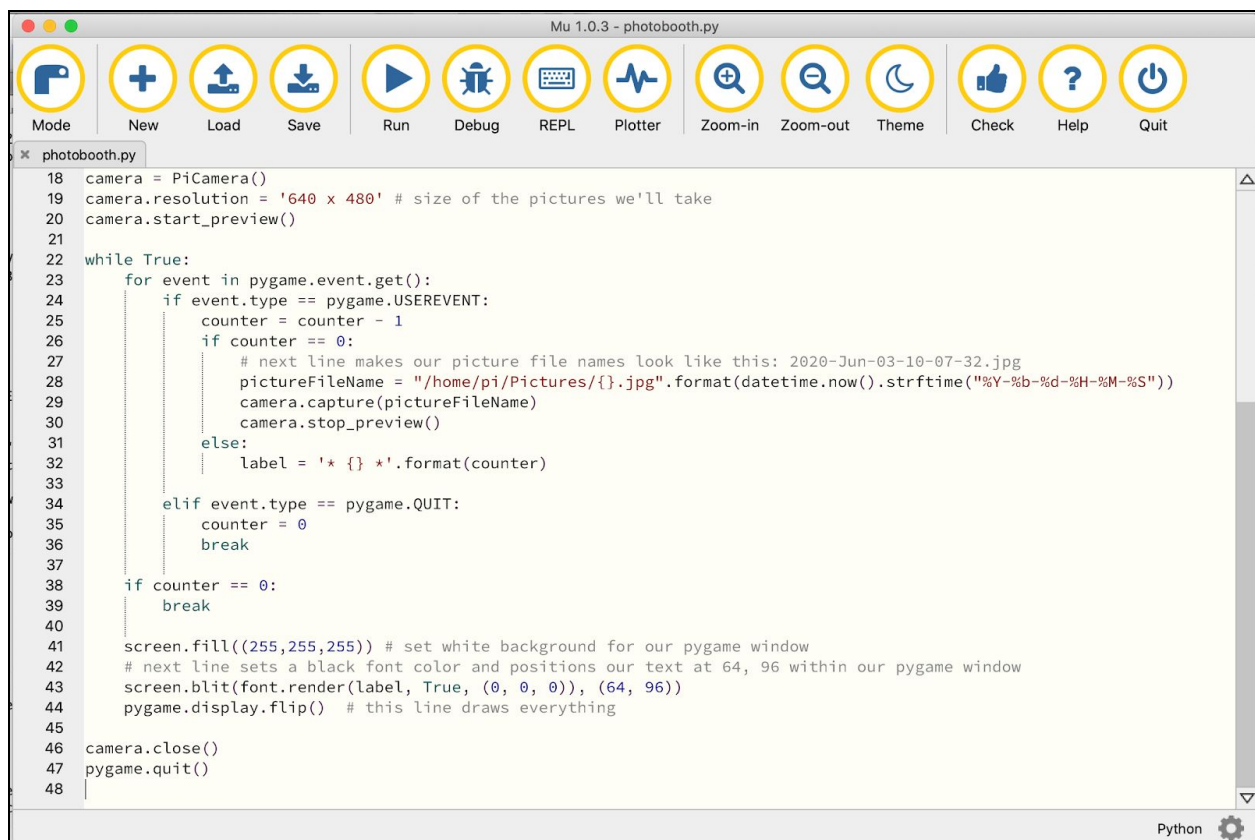

```
11
12 counter = 5
13 label = '* {} *'.format(counter)
14
15 font = pygame.font.SysFont('Arial Bold', 80) # set an 80 point font for our countdown
16 pygame.time.set_timer(pygame.USEREVENT, 1000) # 1000 milliseconds = 1 second
17
18 camera = PiCamera()
19 camera.resolution = '640 x 480' # size of the pictures we'll take
20 camera.start_preview()
21
22 while True:
23     for event in pygame.event.get():
24         if event.type == pygame.USEREVENT:
25             counter = counter - 1
26             if counter == 0:
27                 # next line makes our picture file names look like this: 2020-Jun-03-10-07-32.jpg
28                 pictureFileName = "/home/pi/Pictures/{}.jpg".format(datetime.now().strftime("%Y-%b-%d-%H-%M-%S"))
29                 camera.capture(pictureFileName)
30                 camera.stop_preview()
31             else:
32                 label = '* {} *'.format(counter)
33
34         elif event.type == pygame.QUIT:
35             counter = 0
36             break
37
38     if counter == 0:
39         break
40
41
```

In line 22 we create an “endless loop” by stating that anything we add inside of this loop will run forever, or until we purposely break out of the loop. In python, we indent the lines of code beneath a loop to signify that the code runs “inside of the loop”. Note that lines 23 through 44 are indented beneath the “while True” loop.

Lines 23 through 36 represent the pygame “event loop”. Line 23 loops a new variable we are calling “event” over a list of the events (the event queue) that the pygame window is receiving. For example, if you were to move your mouse while our countdown window was open, a “mouse move” event would be added to the pygame window event queue. However, we only need to be concerned with our one-second timer event; on line 24 we look to see if the most recent event in the event queue was our one-second timer `USEREVENT`.

If we do receive a `USEREVENT`, then we reduce the value of our variable *counter* (initially set to a value of 5) by a value of one. Once the value of *counter* is equal to zero (line 26), we then create a filename for our picture based upon the current date and time, and we take the picture with the code found on lines 29 and 30. If the value of *counter* is greater than zero, then we simply update our *label* variable to the current value of *counter*. We will display the updated *label* variable in our window. Note that we have also indented lines 27 - 30 beneath our conditional statement (i.e. `if counter == 0`) on line 26, which is python’s convention.

Outside of our event loop (lines 38-39), if the *counter* variable is equal to zero (meaning we know we took the picture) then we add the means to break out of our endless “while True” loop using python’s `break` command, thereby ending our program.

```
18 camera = PiCamera()
19 camera.resolution = '640 x 480' # size of the pictures we'll take
20 camera.start_preview()
21
22 while True:
23     for event in pygame.event.get():
24         if event.type == pygame.USEREVENT:
25             counter = counter - 1
26             if counter == 0:
27                 # next line makes our picture file names look like this: 2020-Jun-03-10-07-32.jpg
28                 pictureFileName = "/home/pi/Pictures/{}.jpg".format(datetime.now().strftime("%Y-%b-%d-%H-%M-%S"))
29                 camera.capture(pictureFileName)
30                 camera.stop_preview()
31             else:
32                 label = '* {} *'.format(counter)
33
34         elif event.type == pygame.QUIT:
35             counter = 0
36             break
37
38     if counter == 0:
39         break
40
41     screen.fill((255,255,255)) # set white background for our pygame window
42     # next line sets a black font color and positions our text at 64, 96 within our pygame window
43     screen.blit(font.render(label, True, (0, 0, 0)), (64, 96))
44     pygame.display.flip() # this line draws everything
45
46 camera.close()
47 pygame.quit()
48
```

With lines 41 - 44 (still within our “while True” loop) we fill our pygame’s window background color to white (line 41), and update the screen to include our label value (i.e. what the current counter variable’s count is set to). On line 44 we display (or update) our pygame window on our Raspberry Pi’s screen.

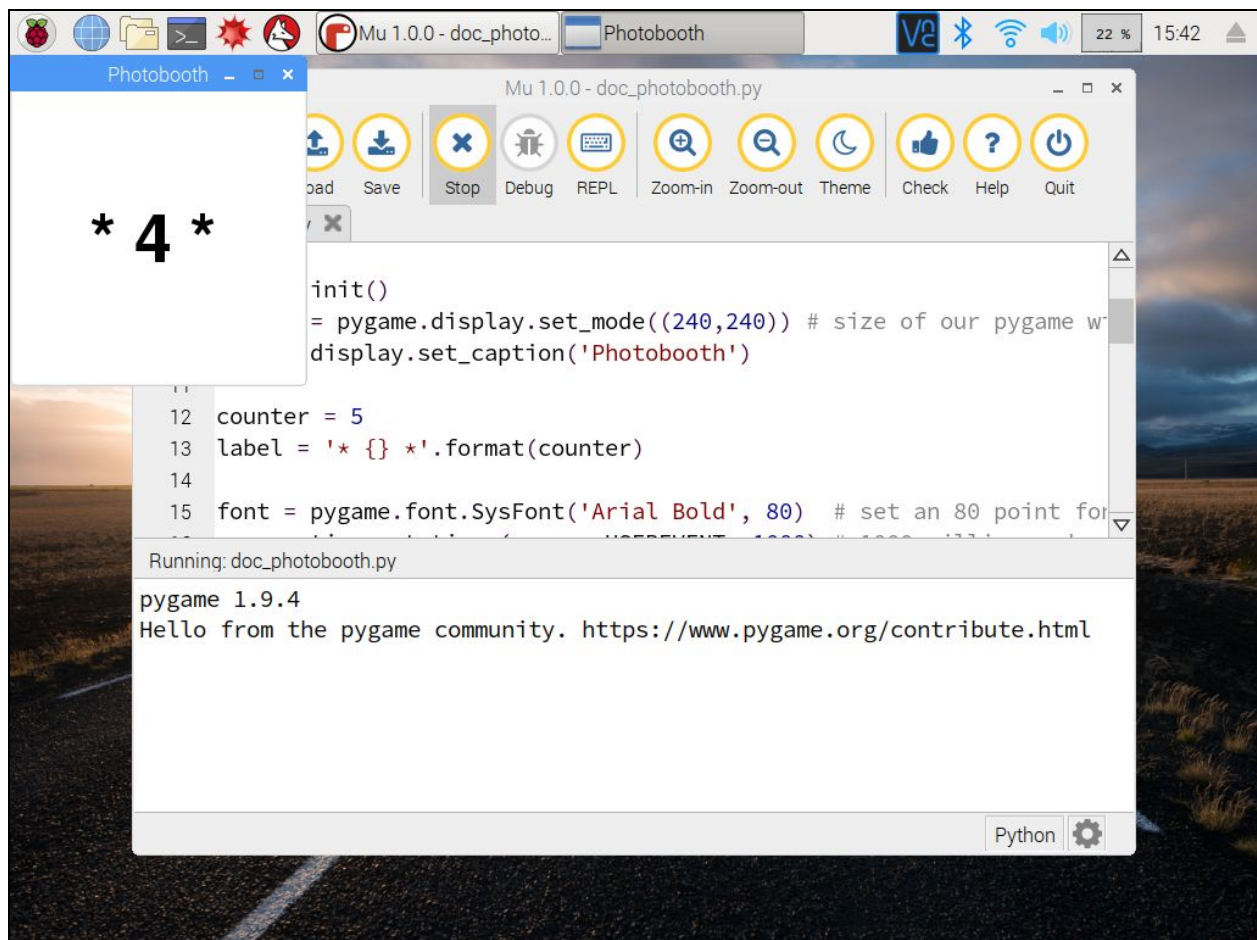

Once we break out of the “while True” loop we do a few cleanup tasks in lines 46 and 47; closing the camera and as well the pygame engine before our program ends.

## **STEP #2 RUN (and debug) your new photobooth program!**

Copying someone else’s code is a great way of learning how to program! Once you get the code running and understand it a bit, you can make some changes to it, like changing the window or font sizes, for example, to learn and make the code your own.

In reality, it's nearly IMPOSSIBLE to copy 40+ lines of unfamiliar code without making an error! Don't be surprised (in fact you can EXPECT) that your code won't run the first time you try it. Don't give up - learning to program requires patience and persistence!

With that being said, let's go ahead and click on the mu editor's RUN button and try to run our code. One of two things will happen: (1) a small window will appear in the upper left corner of our screen, counting down to zero:

... or (2) an error message will appear in a window beneath our code.

```
Mode New Load Save Stop Debug REPL Zoom-in Zoom-out Theme Check Help Quit
```

```
doc_photobooth.py x
```

```
1 import os, pygame
2 from datetime import datetime
3 from picamera import PiCamera
4
5 # create our pygame window in the upper left corner of the screen
6 os.environ['SDL_VIDEO_WINDOW_POS'] = '0,0'
7
8 pygame.init()
9 screen = pygame.display.setmode((240,240)) # size of our pygame window
```

```
Running: doc_photobooth.py
pygame 1.9.4
Hello from the pygame community. https://www.pygame.org/contribute.html
Traceback (most recent call last):
  File "/home/pi/mu_code/doc_photobooth.py" line 9, in <module>
    screen = pygame.display.setmode((240,240)) # size of our pygame window
AttributeError: module 'pygame.display' has no attribute 'setmode'
>>>
```

Python

99% of the time the error will pertain to syntax that was not copied exactly. Usually a line number is provided within the error message that will help you identify the line (or lines) to reexamine within your code. In the example above we typed in “setmode” in line 9 but we should have typed “set\_mode”. This might not be the error you had, but yours will likely be very similar (and don’t be surprised if you have more than one error!).

If you don’t see a RUN button on the mu editor, then your code already ran (or tried to) and the STOP button appears in the RUN button’s place. Click on the STOP button to replace the STOP button with the RUN button. Click on the RUN button to run your code (after making corrections of course!).

Once your code works, you can click on the STOP/RUN button a number of times and create some “photobooth” works of art! The photos that you are creating will appear within the Raspberry Pi’s /home/pi/Pictures folder; you can use the Raspberry Pi folder tool to view them.

If the photobooth program was fun, then you’ll certainly want to move on to the next section and create a **SLIDESHOW program using python** that will create a slideshow of all of the pictures you took with the photobooth on that day. Now that you have some coding experience, this next python program will be even easier!

The following page contains the entire code listing for your convenience:

```

# PHOTOBOOTH PROGRAM (see: http://github/bhontz/GSOCraspi/code/photobooth.py)
import os, pygame
from datetime import datetime
from picamera import PiCamera

# create our pygame window in the upper left corner of the screen
os.environ['SDL_VIDEO_WINDOW_POS'] = '0,0'

pygame.init()
screen = pygame.display.set_mode((240,240)) # size of our pygame window
pygame.display.set_caption('Photobooth')

counter = 5
label = '* {} *'.format(counter)

font = pygame.font.SysFont('Arial Bold', 80) # set an 80 point font for our countdown
pygame.time.set_timer(pygame.USEREVENT, 1000) # 1000 milliseconds = 1 second

camera = PiCamera()
camera.resolution = '640 x 480' # size of the pictures we'll take
camera.start_preview()

while True:
    for event in pygame.event.get():
        if event.type == pygame.USEREVENT:
            counter = counter - 1
            if counter == 0:
                # next line makes our picture file names look like this:
                2020-Jun-03-10-07-32.jpg
                pictureFileName =
                "/home/pi/Pictures/{}.jpg".format(datetime.now().strftime("%Y-%b-%d-%H-%M-%S"))
                camera.capture(pictureFileName)
                camera.stop_preview()
            else:
                label = '* {} *'.format(counter)

        elif event.type == pygame.QUIT:
            counter = 0
            break

    if counter == 0:
        break

    screen.fill((255,255,255)) # set white background for our pygame window
    # next line sets a black font color and positions our text at 64, 96 within our pygame
window
    screen.blit(font.render(label, True, (0, 0, 0)), (64, 96))
    pygame.display.flip() # this line draws everything

camera.close()
pygame.quit()

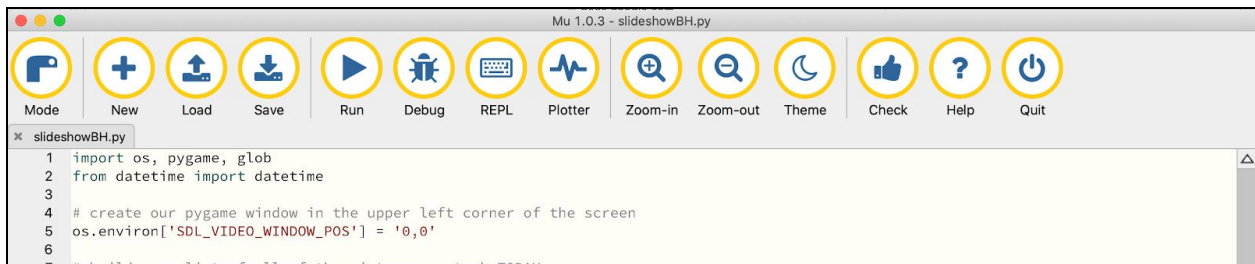

```

# BUILD YOUR OWN SLIDESHOW with PYTHON

## STEP #1 open up the MU python programming environment

Refer to the PHOTOBOTH activity documentation if you have forgotten how to open the MU programming environment and create a new program. Save the program as “slideshowFL” where **F** is the first character of your first name and **L** is the first character of your last name.

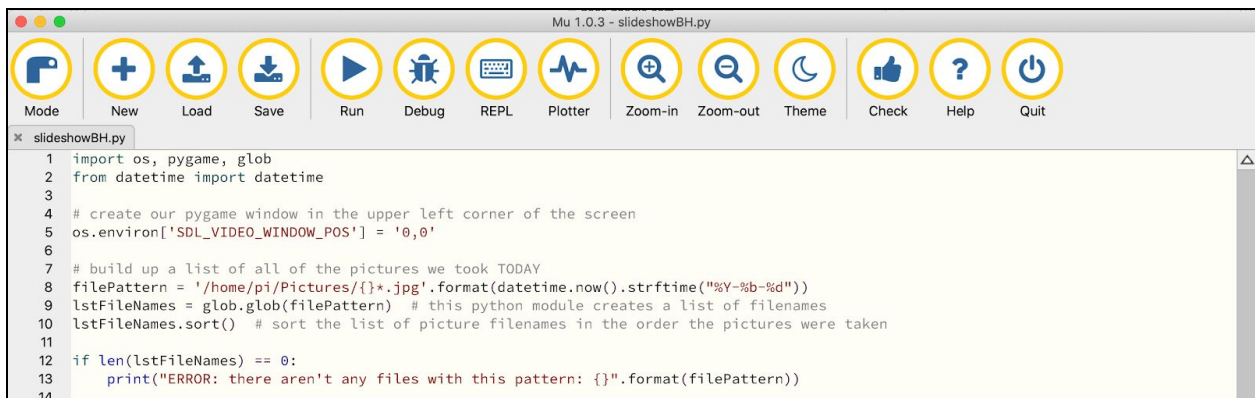

As with our PHOTOBOTH program, we start by including a few external modules into our program as shown below. In our slideshow program, we don’t need the picamera module as we won’t be taking pictures. We do however, need a new external module (glob) to help us read the filenames from a folder. Additionally, just like in our photobooth program, on line 5 we set an environment variable (using the imported os module) to specify where our pygame window is drawn on our Raspberry Pi’s screen.

The screenshot shows the MU Python IDE interface. The title bar reads "Mu 1.0.3 - slideshowBH.py". The toolbar contains icons for Mode, New, Load, Save, Run, Debug, REPL, Plotter, Zoom-in, Zoom-out, Theme, Check, Help, and Quit. The code editor displays the following Python code:

```
1 import os, pygame, glob
2 from datetime import datetime
3
4 # create our pygame window in the upper left corner of the screen
5 os.environ['SDL_VIDEO_WINDOW_POS'] = '0,0'
6
7 # build up a list of all of the pictures we took TODAY
```

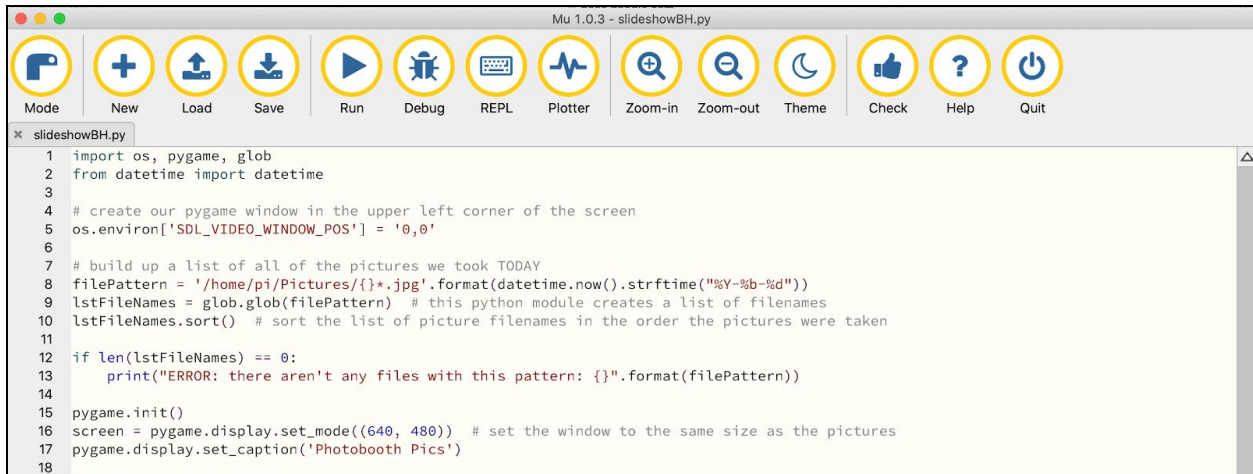

In lines 7 - 13, we use the glob module to search for all of the files beginning with today’s date (example: %Y-%b-%d = 2020-Jun-3) and we return the filenames that match this “file pattern” into a variable that we call *lstFileNames*, or “list of file names”. In line 10 we sort this list by filename, and since a timestamp is part of our filename, the list will be sorted in the order that the pictures were taken. Lines 12 and 13 allow us to report an error if there weren’t any pictures taken today (meaning, we didn’t use the photobooth program before the slideshow program).

The screenshot shows the same MU Python IDE interface as before, but with more code in the editor:

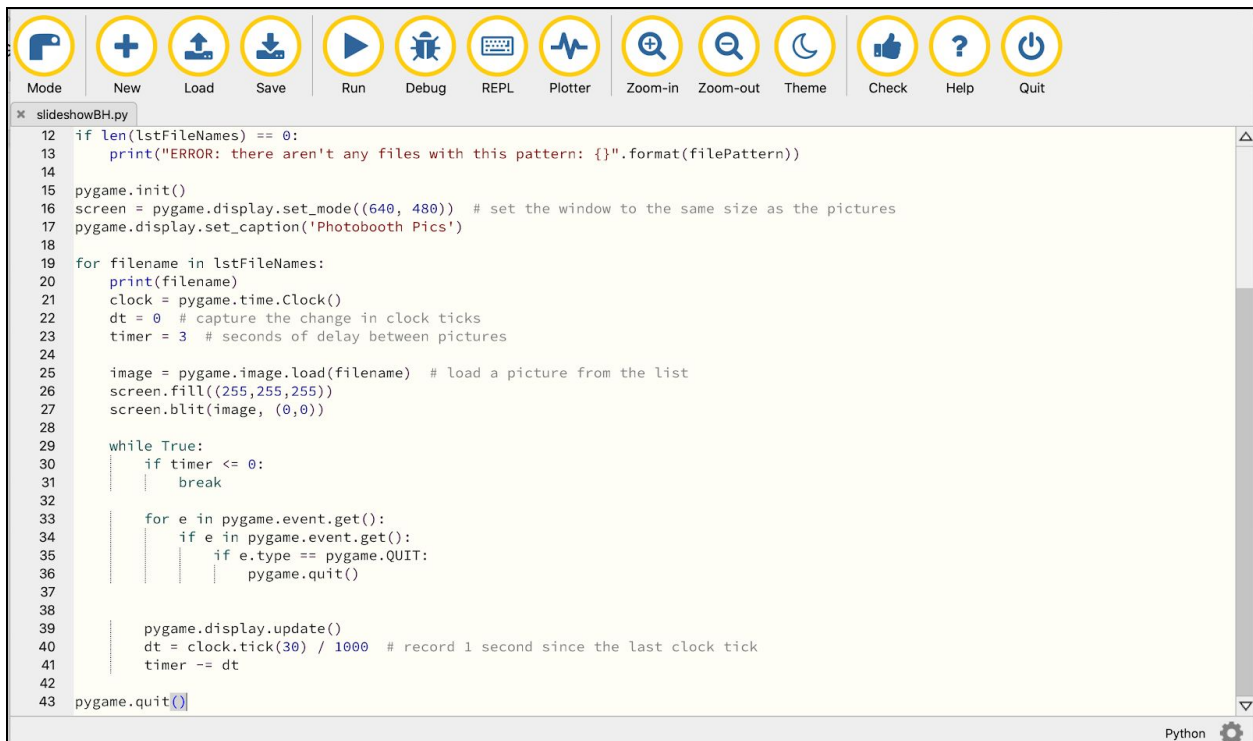

```
8 filePattern = '/home/pi/Pictures/{}'.format(datetime.now().strftime("%Y-%b-%d"))
9 lstFileNames = glob.glob(filePattern) # this python module creates a list of filenames
10 lstFileNames.sort() # sort the list of picture filenames in the order the pictures were taken
11
12 if len(lstFileNames) == 0:
13     print("ERROR: there aren't any files with this pattern: {}".format(filePattern))
14
```

In lines 15 - 16 we initialize the pygame system, then set our pygame screen size to 640 x 480 pixels, which is the same size of the pictures that we took with the photobooth program. In line 17 we set a caption for the pygame window.

```
1 import os, pygame, glob
2 from datetime import datetime
3
4 # create our pygame window in the upper left corner of the screen
5 os.environ['SDL_VIDEO_WINDOW_POS'] = '0,0'
6
7 # build up a list of all of the pictures we took TODAY
8 filePattern = '/home/pi/Pictures/{:}.jpg'.format(datetime.now().strftime("%Y-%b-%d"))
9 lstFileNames = glob.glob(filePattern) # this python module creates a list of filenames
10 lstFileNames.sort() # sort the list of picture filenames in the order the pictures were taken
11
12 if len(lstFileNames) == 0:
13     print("ERROR: there aren't any files with this pattern: {}".format(filePattern))
14
15 pygame.init()
16 screen = pygame.display.set_mode((640, 480)) # set the window to the same size as the pictures
17 pygame.display.set_caption('Photobooth Pics')
18
```

Next, starting from line 19, we loop over the list of our picture filenames, or in other words, the pictures that we took today using the photobooth program. We print the filename out (will print out at the bottom of the MU editor window) and we set a timer which we use to determine how long each picture is shown. Specifically, in line 23, we are setting the value of the variable *timer* to 3, meaning each picture will be displayed for 3 seconds before changing to the next.

```
12 if len(lstFileNames) == 0:
13     print("ERROR: there aren't any files with this pattern: {}".format(filePattern))
14
15 pygame.init()
16 screen = pygame.display.set_mode((640, 480)) # set the window to the same size as the pictures
17 pygame.display.set_caption('Photobooth Pics')
18
19 for filename in lstFileNames:
20     print(filename)
21     clock = pygame.time.Clock()
22     dt = 0 # capture the change in clock ticks
23     timer = 3 # seconds of delay between pictures
24
25     image = pygame.image.load(filename) # load a picture from the list
26     screen.fill((255,255,255))
27     screen.blit(image, (0,0))
28
29     while True:
30         if timer <= 0:
31             break
32
33         for e in pygame.event.get():
34             if e in pygame.event.get():
35                 if e.type == pygame.QUIT:
36                     pygame.quit()
37
38         pygame.display.update()
39         dt = clock.tick(30) / 1000 # record 1 second since the last clock tick
40         timer -= dt
41
42 pygame.quit()
```

In lines 25 - 27, we set up our pygame window by first loading in the current loop iteration's filename, setting the pygame window's background to white, and then initialize the screen (screen.blit) to include the image file we've loaded.

We then enter the endless pygame loop (line 29), which we break out of when our timer value counts down to 0. Just as within our photobooth file, we start a pygame window event loop, which pygame requires. Unlike our photobooth, we really aren't listening for a specific event.

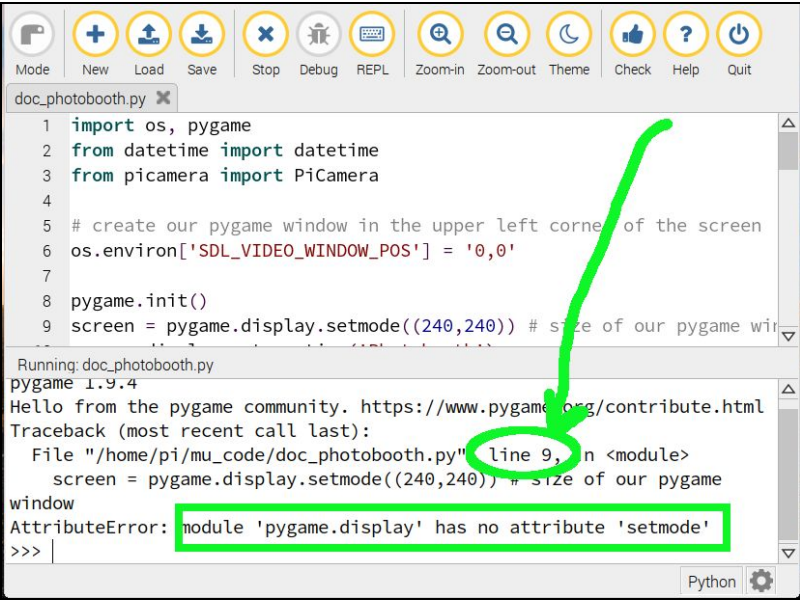

After checking the pygame event queue, we update our pygame window display (line 39) which actually displays our image on the screen. Line 40 returns the number of clock ticks in one second, and subtracts that amount (one second) from our timer. Once the timer counts down to 0 (3 .. 2 .. 1 .. 0) we break out of our endless "while True" loop on line 29 and we move onto the next picture within the `lstFileNames` list.

Finally, on line 43, we shutdown the pygame system before we end our program.

## **STEP #2 RUN (and debug) your new slideshow program!**

As we mentioned in the photobooth program project, it's nearly IMPOSSIBLE to copy 40+ lines of unfamiliar code without making an error! Don't be surprised (in fact you can EXPECT) that your code won't run the first time you try it. Don't give up - learning to program requires patience and persistence!

With that being said, let's go ahead and click on the mu editor's RUN button and try to run our code. One of three things will happen: (1) a window will appear in the upper left corner of our screen, containing the first of the photobooth pictures taken today. (2) The error message "ERROR: there aren't any files with this pattern: YYYY-mm-dd" will appear (YYYY-mm-dd will be an actual date, like 2020-Jun-3) at the bottom of the MU editor's window. Try to use the photobooth program to take some pictures and then run the slideshow program again. (3) an error message will appear resulting from an error we made copying a line of code.

The screenshot shows the Mu Editor interface. The top toolbar includes buttons for Mode, New, Load, Save, Stop, Debug, REPL, Zoom-in, Zoom-out, Theme, Check, Help, and Quit. The editor window displays a Python script named `doc_photobooth.py` with the following code:

```
1 import os, pygame
2 from datetime import datetime
3 from picamera import PiCamera
4
5 # create our pygame window in the upper left corner of the screen
6 os.environ['SDL_VIDEO_WINDOW_POS'] = '0,0'
7
8 pygame.init()
9 screen = pygame.display.setmode((240,240)) # size of our pygame window
```

Below the code editor, the output window shows the following text:

```
Running: doc_photobooth.py
pygame 1.9.4
Hello from the pygame community. https://www.pygame.org/contribute.html
Traceback (most recent call last):
  File "/home/pi/mu_code/doc_photobooth.py", line 9, in <module>
    screen = pygame.display.setmode((240,240)) # size of our pygame window
AttributeError: module 'pygame.display' has no attribute 'setmode'
```

A green arrow points from the `setmode` method call in line 9 of the code to the `setmode` attribute in the error message. The error message is highlighted with a green box.

As an example, in line 16 we should have copied `pygame.display.set_mode`, but we inadvertently copied `pygame.display.setmode` instead, which raised the error above (although the line number would say line 16 in this case).

Once you have corrected any errors, continue to press the STOP button (which will change that button to RUN) and then RUN to play your slideshow! Don't forget you can go back and take a few more pictures with your photobooth program which will be automatically added to your slideshow. Here's the entire listing of the slideshow program for convenience:

```
# SLIDESHOW PROGRAM (see: http://github/bhontz/GSOCraspi/code/slideshow.py)
import os, pygame, glob
from datetime import datetime

# create our pygame window in the upper left corner of the screen
os.environ['SDL_VIDEO_WINDOW_POS'] = '0,0'

# build up a list of all of the pictures we took TODAY
filePattern = '/home/pi/Pictures/{ }*.jpg'.format(datetime.now().strftime("%Y-%b-%d"))
lstFileNames = glob.glob(filePattern) # this python module creates a list of filenames
lstFileNames.sort() # sort the list of picture filenames in the order the pictures were
taken

if len(lstFileNames) == 0:
    print("ERROR: there aren't any files with this pattern: {}".format(filePattern))

pygame.init()
screen = pygame.display.set_mode((640, 480)) # set the window to the same size as the
pictures
pygame.display.set_caption('Photobooth Pics')

for filename in lstFileNames:
    print(filename)
    clock = pygame.time.Clock()
    dt = 0 # capture the change in clock ticks
    timer = 3 # seconds of delay between pictures

    image = pygame.image.load(filename) # load a picture from the list
    screen.fill((255,255,255))
    screen.blit(image, (0,0))

    while True:
        if timer <= 0:
            break

        for e in pygame.event.get():
            if e in pygame.event.get():
                if e.type == pygame.QUIT:
                    pygame.quit()

        pygame.display.update()
        dt = clock.tick(30) / 1000 # record 1 second since the last clock tick
        timer -= dt

pygame.quit()
```
